Fetal ascites is an infrequent anomaly. The prognosis for fetal and neonatal survival is poor, especially with the
development of ascites before 24 weeks' gestation. The spontaneous remission of severe fetal ascites without
intrauterine treatment, especially with an uncomplicated neonatal outcome, is extremely rare.
We report a case of documented fetal ascites at 19 weeks' gestation. The workup for immunologic and non immunologic
causes was negative. Serial ultrasound examination showed ascites at 19 and 33 weeks' gestation. A complete resolution
of the ascites was noted at 6 months after birth. Spontaneous resolution of fetal ascites, with a good prognosis, can
occur in cases with an idiopathic etiology
